**Keywords**: DNA, lipid, vesicle

In the molecular robotics project, a planned molecular robot that is based on a vesicle or a gel as a body consists of molecular sensors, molecular computers, and molecular actuators. These components are communicated with single-stranded DNAs each other. We covered a development of molecular sensor that was a conjugated molecule between DNA strands and lipid.\textsuperscript{[1]} This sensor molecule located on a surface of vesicle could hybridize with a complementary DNA/RNA strand that represented an environmental information. The hybridization caused a shape change of the molecular sensor, consequently a single-stranded DNA was released into an inner water pool of vesicle. The released DNA was a trigger for molecular computers encapsulated in the vesicle.
